Cohost pricing calculator — Notion template

A working Notion database that holds your pricing assumptions per property, calculates your needed percentage, surfaces a recommended offer structure, and tracks what you actually charge after the engagement starts.

This PDF is the README + setup guide. The actual Notion database template is delivered as a private Notion page link after purchase. You duplicate it into your own Notion workspace and own the data.

What you get

- A Notion database with one row per property
- A template row pre-filled with the formulas below
- A "comp set" linked database for the 3-5 properties you compare each listing against
- A "monthly tracker" view that compares your predicted fees to actual payouts each month
- A "renegotiation queue" view that flags engagements where you have hit your triggers for a price increase

The 12 fields on each property row

- 1. Property name
- 2. Address (city for privacy)
- 3. Listing URL
- 4. Owner name + contact
- 5. Engagement start date
- 6. Engagement end date (renewal)
- 7. Hours per month I expect (your estimate)
- 8. Target hourly rate
- 9. Expected monthly revenue (your estimate)
- 10. My needed percentage (auto-calculated from 7, 8, 9)
- 11. Comp set median cohost fee (you update manually)
- 12. Actual fee charged (often = 10 if comp set says so)

The auto-calculated fields

```
needed_pct = (hours_per_month * target_hourly_rate) / expected_monthly_revenue
recommended_offer = IF needed_pct < comp_set_median * 0.85 THEN "test lower" ELSE IF
needed_pct > comp_set_median * 1.15 THEN "premium" ELSE "standard"
monthly_take = expected_monthly_revenue * 12 * pct / 12
effective_hourly = monthly_take / hours_per_month
```

These formulas use Notion's formula fields. After duplicating the template, you don't need to maintain them — paste them in once.

The 4 views

Pipeline view

Kanban with columns: Lead → Discovery Call → Audit Sent → Negotiating → Signed → Active. Each column sums the expected monthly take, so you see your pipeline's revenue at a glance.

Active view

Table of every property where `engagement_start <= today <= engagement_end`. Sort by `needed_pct` descending to surface the under-priced ones first.

Renegotiation queue

Filtered view: properties where the engagement ends in <60 days AND `effective_hourly > target_hourly_rate * 1.2`. These are the ones you call first when renewal comes up.

Monthly tracker

Calendar view: one entry per property per month. Compare `actual_payout` to `expected_revenue`. Surfaces the ones that are drifting off plan.

How to use this for real

Start with one row — your current or first property. Fill in fields 1-9 honestly. Let the formulas calculate 10-12. Compare `needed_pct` to `comp_set_median`. If your number is way off, you have a positioning problem, not a calculator problem.

Add the comp set as a second database. Link each property row to its 3 comps. Update `comp_set_median` monthly.

Once you have 5 properties, the renegotiation queue is where this pays for itself: you stop forgetting to renegotiate, you stop underselling.
